

Running the example postman collection

Postman is popular API client that makes it easy for developers to test APIs. This brief guide provides instructions on how to use the postman collections accompanying the developer onboarding pack for the Shell Card Transaction Data API.

The team at Shell have prepared postman collections that provides an end-to-end walkthrough of the most common use cases. There are working examples for all API end-points available in the Shell Card Transaction Data API with API calls chained to illustrate the use cases.

Once you have received your Shell ApiKey and Secret, then you're only a few clicks away from familiarising yourself with the Shell Card Transaction Data API.

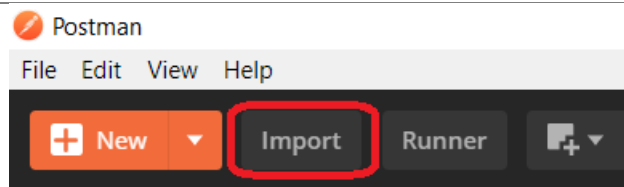

Running the Shell postman collections

Follow these steps for both collections that come with the developer onboarding pack:

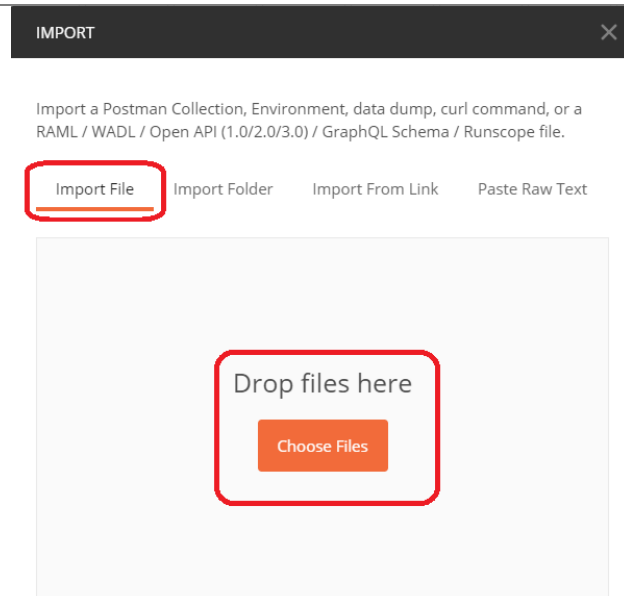

- Shell - Card Transaction Data API (Fees)
- Shell - Card Transaction Data API (Priced)

1 Download and install the postman tool from <https://www.postman.com/>

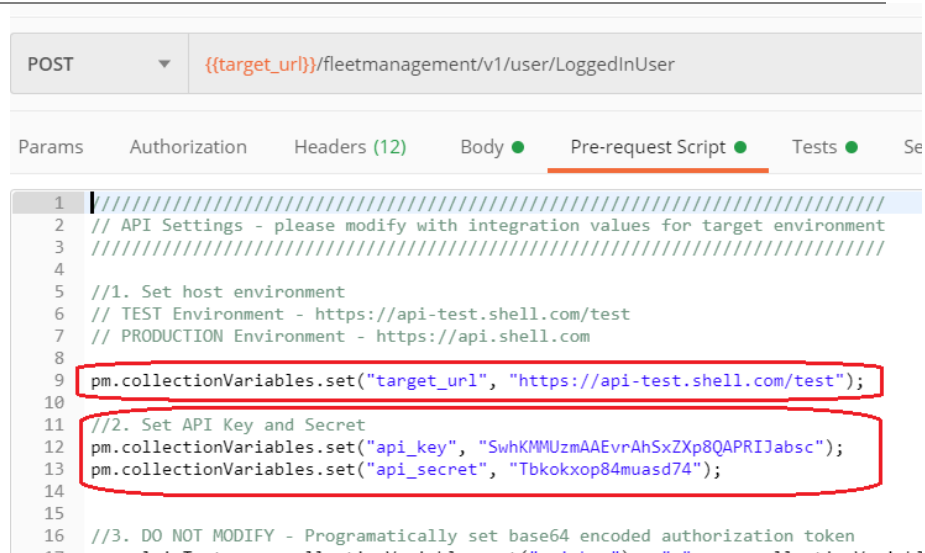

2 Launch Postman and click the 'Import' button, which is usually located on the top-left of the application.

3 On the Import screen, drop the Shell collection file 'Shell - Card Transaction Data API.postman_collection.json' from your local PC. Or click 'Choose Files' to select the file.

- Click on the *'Pre-request Script'* tab and populate the postman variables *"target_url"*, *"api_key"* and *"api_secret"*.

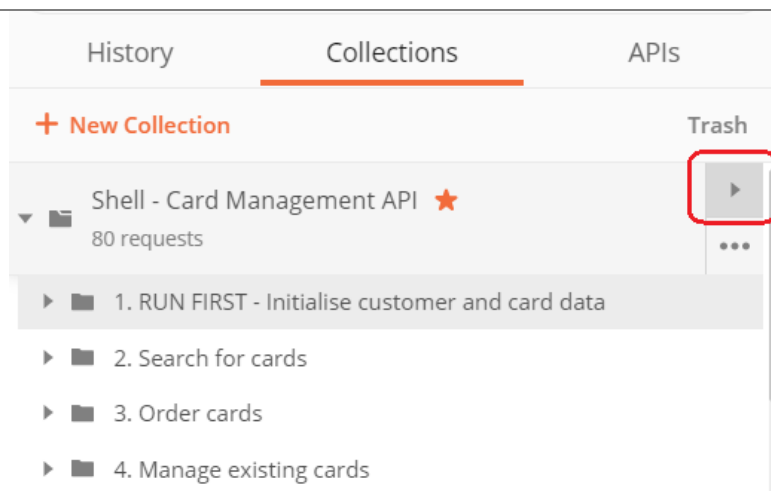

You're ready to Go!

Start executing the API calls in the collection sequentially for a walkthrough of the common use cases.

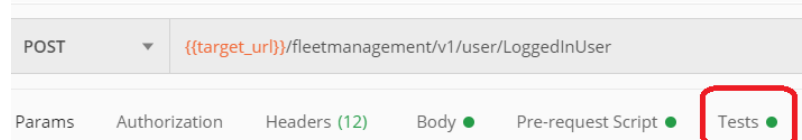

- Click on each of the requests under the folder '1. RUN FIRST - Initialise customer and search data' and execute each in order by clicking the 'Send' button. This will initialise the default data required by the other API calls in the collection.

Useful Postman Tips

- 1 View the collection documentation in Postman by clicking the arrow toggle next to the collection name. This will load the documentation on the right.

- 2 Check the Tests' tab for each of the requests in the collection. If it's highlighted with a green circle, then this indicates we've added custom code to process the results of the API call and store response data in local postman variables.

- 3 Click the 'Code' link in postman to view the API call in your programming language of choice.
